1 Finite Automata and Regular Languages

1.1 Simple Constructions on Finite Automata

1. Give a deterministic finite automaton over the alphabet \{a, b\} which accepts all strings containing no more than two consecutive occurrences of the same input letter. (For example, \textit{abba} should be accepted but not \textit{abaaab}.)

2. Convert the nondeterministic automaton given below to an equivalent deterministic one using the subset construction. Omit inaccessible states. Draw the graph of the resulting DFA.

\[
\begin{array}{c|cc}
| & a & b \\
\hline
\rightarrow q_1 & \{q_2\} & \emptyset \\
\rightarrow q_2 & \emptyset & \{q_1, q_3\} \\
q_3 & \{q_2, q_3\} & \{q_1\} \\
\end{array}
\]

\textbf{Solution:} (presented as a table)

\[
\begin{array}{c|cc}
| & a & b \\
\hline
\rightarrow \{q_1, q_2\} & F & \{q_2\} & \{q_1, q_3\} \\
\rightarrow \{q_1, q_3\} & F & \{q_2, q_3\} & \{q_1\} \\
\rightarrow \{q_2, q_3\} & F & \{q_2, q_3\} & \{q_1, q_3\} \\
\rightarrow \{q_1\} & \emptyset & \emptyset & \emptyset \\
\rightarrow \{q_2\} & F & \emptyset & \{q_1, q_3\} \\
\rightarrow \emptyset & \emptyset & \emptyset & \emptyset \\
\end{array}
\]

3. Convert the nondeterministic automaton given below to an equivalent deterministic one using the subset construction. Omit inaccessible states. Draw the graph of the resulting DFA.

\[
\begin{array}{c|cc}
| & a & b \\
\hline
\rightarrow q_1 & q_1, q_2 & q_3 & F \\
\rightarrow q_2 & q_4 & F \\
\rightarrow q_3 & q_4 & - \\
\rightarrow q_4 & - & q_1, q_4 \\
\end{array}
\]

\textbf{Solution:} (given as a table)
4. Convert the nondeterministic automaton given below to an equivalent deterministic one using the subset construction (textbook Lecture 6). Omit inaccessible states. Draw the graph of the resulting DFA.

```
  a | b
--|---
→ | {q1, q3} | {q1, q2, q4} | {q3} | F
{q1, q2, q4} | {q1, q2} | {q1, q3, q4} | F
{q1, q3, q4} | {q1, q2, q4} | {q1, q3, q4} | F
{q1, q2} | {q1, q2} | {q3, q4} | F
{q3, q4} | {q4} | {q1, q4} |
{q1, q4} | {q1, q2} | {q1, q3, q4} | F
{q4} | {} | {q1, q4} |
{q3} | {q4} | {} |
{} | {} | {} |
```

Solution: (as a table)

```
  a | b
--|---
→ | {q0} | {q2} | ∅ |
{q0, q1} | F | {q0, q2} | ∅ |
q1 F | {q0, q2} | ∅ |
q2 F | ∅ | {q1, q2} |
```

5. Convert the nondeterministic automaton given below to an equivalent deterministic one using the subset construction, textbook Lecture 6. Omit inaccessible states. Draw the graph of the resulting DFA.

```
  a | b
--|---
→ | {q0, q1} | F | {q0, q2} | ∅ |
{q0, q2} | F | {q2} | {q1, q2} |
{q1, q2} | F | {q0, q2} | {q1, q2} |
{q2} | F | ∅ | {q1, q2} |
∅ | ∅ | ∅ |
```

Solution: Easy: has 8 states, and hence no inaccessible ones!

6. Give a (as simple as possible) nondeterministic finite automaton for the language defined by the regular expression $ab^* + a(ba)^*$. Apply the subset construction to obtain an equivalent deterministic automaton. Draw the graph of this DFA, omitting inaccessible states.

7. Give a DFA for the language defined by the regular expression $a^*a$, and another one for $a(ba)^*$. The union of the two DFAs defines a nondeterministic FA for the language $a^*a + a(ba)^*$.

(a) Apply the subset construction to this NFA to produce a DFA for this language. Omit the inaccessible states. Draw the graph of the resulting DFA.

(b) Is this DFA minimal? If not, which states are equivalent?
1.2 Closure Properties of Regular Languages

8. Show that regular languages are closed under doubling: If language \( L \) is regular, then so is the language \( L_2 \overset{\text{def}}{=} \{ \text{two } x \mid x \in L \} \), where string doubling is defined inductively by two \( \epsilon \overset{\text{def}}{=} \epsilon \) and two \( xa \overset{\text{def}}{=} (\text{two } x) \cdot aa \).

Solution: Here is a standard solution using finite automata; alternative solutions exist using regular expressions or homomorphisms.

Let \( L \) be regular. Then there is an NFA \( N = (Q_N, \Sigma, \Delta_N, S_N, F_N) \) such that \( L(N) = L \). Define another NFA, \( N_2 \), as follows: start with \( N \) and replace every edge \( q \overset{a}{\rightarrow} q' \) with two edges \( q \overset{a}{\rightarrow} q'' \) and \( q'' \overset{a}{\rightarrow} q' \) by inserting (for each edge!) a new state \( q'' \). We can formalize this idea by taking as states of \( N_2 \) the states of \( N \) plus the edges of \( N \), the latter represented for example as the set of triples \( \{(q_N, a, q'_N) \mid q_N \in Q_N, q'_N \in \Delta_N(q_N, a)\} \). So, we can define \( N_2 \) as follows:

- \( Q_{N_2} \overset{\text{def}}{=} Q_N \cup \{(q_N, a, q'_N) \mid q_N \in Q_N, q'_N \in \Delta_N(q_N, a)\} \)
- \( \Delta_{N_2}(q_N, a) \overset{\text{def}}{=} Q_N \cup \{(q_N, a, q'_N) \mid q'_N \in \Delta_N(q_N, a)\} \) and \( \Delta_{N_2}(q_N, b, q'_N, a) \overset{\text{def}}{=} \) if \( a = b \) then \( \{q'_N\} \) else \( \emptyset \)
- \( S_{N_2} \overset{\text{def}}{=} S_N \)
- \( F_{N_2} \overset{\text{def}}{=} F_N \)

It is straightforward to show that, for the so constructed NFA, \( L(N_2) = L_2 \), thus implying that \( L_2 \) is regular. Hence, regular languages are closed under doubling.

9. Let \( A \subseteq \Sigma^* \) be a language. We define its prefix closure as:

\[
\text{pref } A = \{ x \in \Sigma^* \mid \exists y \in \Sigma^*. x \cdot y \in A \}
\]

Prove that regular languages are closed under prefixing: if language \( A \) is regular, then so is \( \text{pref } A \).

Solution: Let \( A \subseteq \Sigma^* \) be regular. Then there must be a DFA \( M_A = (Q, \Sigma, \delta, s, F) \) such that \( L(M_A) = A \). Now, based on \( M_A \), define another automaton \( M = (Q, \Sigma, \delta, s, F') \) so that:

\[
F' = \{ q \in Q \mid \exists y \in \Sigma^*. \delta(q, y) \in F \}
\]

We will show that this automaton accepts the language \( \text{pref } A \), and hence that \( \text{pref } A \) is regular.

Claim. \( L(M) = \text{pref } A \)

Proof.

\[
x \in L(M) \iff \exists y \in \Sigma^*. \delta(s, x) \cdot y \in F' \iff \exists y \in \Sigma^*. \delta(s, x \cdot y) \in F \}
\]

10. Consider the following unary operation on languages:

\[
\text{min}(L) = \{ x \in L \mid \text{no proper prefix of } x \text{ is in } L \}
\]

Prove that regular languages are closed under this operation; that is, prove that if language \( A \) is regular, then so is \( \text{min}(A) \).

Solution: Assume \( A \) is regular. (For simplicity, we shall also assume \( \epsilon \notin A \).) Then there is a DFA \( M_A \) accepting \( A \). We construct another DFA \( M'_A \) from \( M_A \) by adding two new states \( q_F \) and \( q_G \), making
the only accepting state of $M'_A$, letting $\delta'(q_F, a) = q_G$ and $\delta'(q_G, a) = q_G$ for every $a \in \Sigma$, and by re-directing all edges pointing to a final state in $M_A$ to point to $q_F$. We can then show $L(M'_A) = \text{min}(A)$ as follows:

\[
x \in L(M'_A) \iff \hat{\delta}(s, x) = q_F \quad \{\text{Def. acceptance and } M'_A\}
\]

\[
x \in \text{min}(A) \quad \{\text{Def. min}(A)\}
\]

thus proving that $\text{min}(A)$ is regular.

### 1.3 DFA State Minimization

11. For the deterministic automaton given below, apply the minimization algorithm of Lecture 14 to compute the equivalence classes of the collapsing relation $\approx$ defined in Lecture 13. Show clearly the computation steps. List the equivalence classes, and apply the quotient construction to derive a minimized automaton. Draw its graph.

\[
\begin{array}{c|cc}
  & a & b \\
\hline
  \rightarrow & q_0 & q_0 \ q_1 \\
  & q_1 & q_2 \ q_3 \\
  & q_2 & q_2 \ q_3 \\
  & q_3 & q_2 \ q_4 \ F \\
  & q_4 & q_0 \ q_1 \\
\end{array}
\]

**Solution:** (incomplete) After applying the minimization algorithm we obtain that $q_0 \approx q_4$ and $q_1 \approx q_2$. Thus we obtain the following minimized automaton (given as a table).

\[
\begin{array}{c|cc}
  & a & b \\
\hline
  \rightarrow & \{q_0, q_4\} & \{q_0, q_4\} \ {q_1, q_2} \\
  & \{q_1, q_2\} & \{q_1, q_2\} \ \{q_3\} \\
  & \{q_3\} & \{q_1, q_2\} \ \{q_0, q_4\} \ F \\
\end{array}
\]

12. For the deterministic automaton given below, apply the minimization algorithm of Lecture 14 to compute the equivalence classes of the collapsing relation $\approx$ defined in Lecture 13. Show clearly the computation steps. List the equivalence classes, and apply the quotient construction to derive a minimized automaton. Draw its graph.

\[
\begin{array}{c|cc}
  & a & b \\
\hline
  \rightarrow & q_1 & q_3 \ q_8 \\
  & q_2 \ F & q_3 \ q_1 \\
  & q_3 & q_8 \ q_2 \\
  & q_4 \ F & q_5 \ q_6 \\
  & q_5 & q_6 \ q_2 \\
  & q_6 & q_7 \ q_8 \\
  & q_7 & q_6 \ q_4 \\
  & q_8 & q_5 \ q_8 \\
\end{array}
\]

**Solution:** With the minimization algorithm we establish that $q_1 \approx q_6 \approx q_8$, $q_2 \approx q_4$ and $q_3 \approx q_5 \approx q_7$. The resulting quotient automaton, presented as a table, is:

\[
\begin{array}{c|cc}
  & a & b \\
\hline
  \rightarrow & \{q_1, q_6, q_8\} & \{q_3, q_5, q_7\} \ {q_1, q_6, q_8} \\
  & \{q_3, q_5, q_7\} & \{q_1, q_6, q_8\} \ {q_2, q_4} \\
  & \{q_2, q_4\} \ F & \{q_3, q_5, q_7\} \ \{q_1, q_6, q_8\} \\
\end{array}
\]
13. For the deterministic automaton given below, apply the minimization algorithm of Lecture 14 of the textbook to compute the equivalence classes of the collapsing relation \( \approx \) defined in Lecture 13.

\[
\begin{array}{c|ccc}
 & a & b \\
\hline
\rightarrow & q_0 \text{F} & q_1 & q_3 \\
 & q_1 & q_2 & q_3 \\
 & q_2 \text{F} & q_5 & q_2 \\
 & q_3 & q_4 & q_1 \\
 & q_4 \text{F} & q_5 & q_4 \\
 & q_5 & q_5 & q_5 \\
\end{array}
\]

(a) Show clearly the computation steps (use tables).
(b) List the computed equivalence classes.
(c) Apply the quotient construction of Lecture 13 to derive the minimized automaton. Draw its graph.

**Solution:** As a table:

\[
\begin{array}{c|ccc}
 & a & b \\
\hline
\rightarrow & \{q_0\} \text{F} & \{q_1, q_3\} & \{q_1, q_3\} \\
 & \{q_1, q_3\} & \{q_2, q_4\} & \{q_1, q_3\} \\
 & \{q_2, q_4\} \text{F} & \{q_5\} & \{q_2, q_4\} \\
 & \{q_5\} & \{q_5\} & \{q_5\} \\
\end{array}
\]

14. For the deterministic automaton given below, apply the minimization algorithm of textbook Lecture 14 to compute the equivalence classes of the collapsing relation \( \approx \) defined in textbook Lecture 13.

\[
\begin{array}{c|cc}
 & a & b \\
\hline
\rightarrow & q_0 & q_2 \text{q_0} \\
 & q_1 & q_0 & q_2 \\
 & q_2 \text{F} & q_4 & q_3 \\
 & q_3 & q_0 & q_4 \\
 & q_4 \text{F} & q_4 & q_1 \\
\end{array}
\]

(a) Show clearly the computation steps (use tables).
(b) List the computed equivalence classes.
(c) Apply the quotient construction of textbook Lecture 13 to derive the minimized automaton. Draw its graph.

**Solution:** (as a table)

\[
\begin{array}{c|ccc}
 & a & b \\
\hline
\rightarrow & \{q_0\} & \{q_2, q_4\} & \{q_0\} \\
 & \{q_1, q_3\} & \{q_0\} & \{q_2, q_4\} \\
 & \{q_2, q_4\} \text{F} & \{q_2, q_4\} & \{q_1, q_3\} \\
\end{array}
\]

1.4 **Myhill–Nerode Relations and Theorem**

15. Consider the language \( L \) defined by the regular expression \((a^* + ba)^*\). Describe the equivalence classes of \( \{a, b\}^* \) w.r.t. the Myhill–Nerode relation \( \equiv_L \) defined by: (cf. equation (16.1) on page 97)

\[
x_1 \equiv_L x_2 \iff \forall y \in \Sigma^*. (x_1 \cdot y \in L \iff x_2 \cdot y \in L)
\]

Present these equivalence classes through regular expressions. Use \( \equiv_L \) to construct a minimal automaton \( M_{\equiv_L} \) (cf. page 91) for the language \( L \), and draw the graph of the automaton.

**Solution:** The states of the quotient automaton are:

\[
\Sigma^*/\equiv_L = \{ L((a + ba)^*) , L((a + ba)^*b) , L((a + ba)^*bb(a + b)^*) \}
\]
16. Recall the Myhill–Nerode Theorem, textbook Lecture 16, with the equivalence relation \( \equiv_A \) on strings defined in equation (16.1). The latter gives rise to the following technique for proving that the minimal DFA for a given regular language \( A \) over \( \Sigma \) has at least \( k \) states:

Identify \( k \) strings \( x_1, \ldots, x_k \) over \( \Sigma \), for which you can show that:

\[ x_i \not\equiv_A x_j \text{ whenever } i \neq j. \]

Then \( \equiv_A \) has at least \( k \) equivalence classes, and hence the desired result.

Now, let \( m \) be an arbitrary but fixed even number. Consider the language \( B \) over \( \{a, b\} \) consisting of all strings of length at least \( m \) which have an equal number of \( a \)'s and \( b \)'s in the last \( m \) positions. Use the technique described above to show that the minimal DFA for language \( B \) has at least \( 2^{m^2} \) states.

**Hint:** Consider the strings of length \( m^2 \).

**Solution:** Consider the set \( X \) of strings of length \( m^2 \) over \( \{a, b\} \). Let \( x, y \in X \) so that \( x \neq y \). Let \( x', y' \) be the shortest suffixes of \( x \) and \( y \) respectively, such that \( |x'| = |y'| \) and \( x' \neq y' \). Then obviously \( \exists a(x') \neq \exists a(y') \). Now let \( z = a^rb^s \), where \( r = m^2 - \exists a(x') \) and \( s = m - (|x'| + r) \). Then \( x \cdot z \in B \) while \( y \cdot z \not\in B \), and hence \( x' \not\equiv_B y' \). Since \( X \) has \( 2^{m^2} \) elements, \( \equiv_B \) has at least \( 2^{m^2} \) equivalence classes, and therefore the minimal DFA for language \( B \) has at least \( 2^{m^2} \) states.

1.5 **Proving Non–regularity of a Language**

17. Apply the Pumping Lemma – in contra–positive form, as a game with the Demon – to show that the following language:

\[ A = \{a^n \mid n \text{ is a power of 2}\} \]

is not regular.

**Solution:** One possible solution is:

(D) Demon picks \( k \).

(W) We pick \( x = \epsilon, y = a^{2^k} \) and \( z = a^{2^k} \). Then \( xyz = a^{2^{k+1}} \) and \( |y| > k \).

(D) Demon picks \( u, v \) and \( w \) so that \( uvw = y = a^{2^k} \) and \( v \neq \epsilon \).

(W) We pick \( i = 2 \).

Then \( xuv^i w = a^{2^{k+1} + l} \) for some \( 0 < l \leq 2^k \). Since \( l < 2^{k+1} \) we have \( 2^{k+1} < 2^{k+1} + l < 2^{k+2} \), and hence \( xuv^i w \not\in A \). We have a winning strategy, and \( A \) is therefore not regular.
2 Pushdown Automata and Context-Free Languages

2.1 Combined Problems

1. Consider the language:

\[ L \overset{\text{def}}{=} \left\{ x \cdot y \in \{a, b\}^+ \mid y = \text{rev} \ x \right\} \]

where \( \text{rev} \ x \) denotes the reverse string of \( x \) (cf. HW 2.2, page 302).

(a) Use the Pumping Lemma to prove that \( L \) is not regular.

**Solution:** As a game with the Demon (cf. Lecture 11):

- Demon picks \( k > 0 \).
- We pick for example \( x = \epsilon, y = a^k, z = bba^k \), and we have \( xyz = a^k bba^k \in L \) and \( |y| \geq k \).
- Demon picks \( wu = y = a^k, v \neq \epsilon \).
- We pick for example \( i = 0 \).

Then \( xuv^i wz = uwz = a^i bba^k \) for some \( j < k \), and hence \( xuv^i wz \not\in A \). We have a winning strategy, and \( L \) is therefore not regular.

(b) Give a context–free grammar \( G \) for \( L \).

**Solution:**

\[ S \rightarrow aa \mid bb \mid aSa \mid bSb \]

(c) Prove your grammar correct (cf. Lecture 20): that is, prove \( L = L(G) \).

**Solution:** We have to prove:

\[ \forall x \in \{a, b\}^+. \ (S \xrightarrow{\gamma} x \iff x \in L) \]

We show the two directions of the equivalence separately.

(⇒) By induction on the length of the derivation of \( x \).

- **Basis** Holds vacuously, since \( S \xrightarrow{0} x \) is false: \( x = S \) is impossible since \( S \not\in \{a, b\}^+ \).
- **Induction Step** Assume \( x' \in L \) for all \( x' \) such that \( S \xrightarrow{\gamma} x' \) (induction hypothesis).

Let \( S \xrightarrow{n+1} x \). Then, we must have \( S \xrightarrow{1} \gamma \) and \( \gamma \xrightarrow{n} x \) for some \( \gamma \in \{a, b, S\}^+ \). But then \( \gamma \) can only be \( aa \) or \( bb \) or \( aSa \) or \( bSb \). The first two cases imply \( n = 0 \) and \( x = \gamma \), and then obviously \( x \in L \). In the case \( \gamma = aSa \), it must be that \( x = ax'a \) and \( S \xrightarrow{n} x' \) for some \( x' \). From the induction hypothesis, we have \( x' \in L \). But \( x = ax'a \), and therefore also \( x \in L \).

The case \( \gamma = bSb \) is similar.

(⇐) By induction on \( |x| \), which is even and positive.

- **Basis** \( |x| = 2 \), then \( x \in L \) implies that \( x \) is either \( aa \) or \( bb \). In both cases \( S \xrightarrow{1} x \) and therefore \( S \xrightarrow{*} x \).
- **Induction Step** Assume \( S \xrightarrow{*} x' \) for all \( x' \in L \) such that \( |x'| = n \) (induction hypothesis).

Let \( |x| = n + 2 \), and let \( x \in L \). It must be that either \( x = ax'a \) or \( x = bx'b \) for some \( x' \) such that \( x' \in L \) and \( |x'| = n \). From the induction hypothesis, \( S \xrightarrow{*} x' \). Then, in the case \( x = ax'a \) we also have \( aSa \xrightarrow{*} ax'a = x \), and since \( S \xrightarrow{1} aSa \), then \( S \xrightarrow{*} x \).

The case \( x = bx'b \) is similar.

(d) Give an NPDA for \( L \).

**Solution:** One possibility is to put \( G \) in GNF:

\[ S \rightarrow aA \mid bB \mid aSA \mid bSB \]
\[ A \rightarrow a \]
\[ B \rightarrow b \]

and then construct the NPDA canonically (cf. Lecture 24):

\[ Q \overset{\text{def}}{=} \{q\} \]
\[ \Sigma \overset{\text{def}}{=} \{a, b\} \]
\[ \Gamma \overset{\text{def}}{=} \{S, A, B\} \]
\[ \delta \defeq \begin{array}{c}
\langle q, S \rangle \xrightarrow{a} \langle q, SA \rangle \\
\langle q, S \rangle \xrightarrow{a} \langle q, A \rangle \\
\langle q, S \rangle \xrightarrow{b} \langle q, SB \rangle \\
\langle q, S \rangle \xrightarrow{b} \langle q, B \rangle \\
\langle q, A \rangle \xrightarrow{a} \langle q, \epsilon \rangle \\
\langle q, B \rangle \xrightarrow{b} \langle q, \epsilon \rangle 
\end{array} \]

2. Consider the language:

\[ A = \{ a^k b^l a^m \mid m = k + l \} \]

(a) Use the closure properties of regular languages to show that \( A \) is not regular.

**Solution:** The language \( L(b^*a^*) \) is regular, but \( A \cap L(b^*a^*) = \{ b^n a^n \mid n \geq 0 \} \), as we already know, is not regular. Since regular languages are closed under intersection, \( A \) is not regular.

(b) Give a context–free grammar \( G \) generating \( A \).

**Solution:** One possibility is:

\[
\begin{align*}
S & \rightarrow aSa \\
B & \rightarrow \epsilon | bBa
\end{align*}
\]

(c) Prove your grammar correct; that is, prove \( S \xrightarrow{\dagger_G} x \iff x \in A \).

**Solution:** The proof is standard, and is made easy by the fact that we already know that \( B \xrightarrow{\dagger_G} x \iff x \in \{ b^n a^n \mid n \geq 0 \} \).

(d) Construct an NPDA accepting \( A - \{ \epsilon \} \) on empty stack. Explain your choice of productions.

**Solution:** One possibility is to build an NPDA with three states, having the following productions:

\[
\begin{align*}
\langle q_0, \bot \rangle & \xrightarrow{a} \langle q_0, C \rangle \\
\langle q_0, \bot \rangle & \xrightarrow{a} \langle q_2, C \rangle \\
\langle q_0, \bot \rangle & \xrightarrow{b} \langle q_1, C \rangle \\
\langle q_0, C \rangle & \xrightarrow{a} \langle q_0, CC \rangle \\
\langle q_0, C \rangle & \xrightarrow{a} \langle q_2, CC \rangle \\
\langle q_0, C \rangle & \xrightarrow{b} \langle q_1, CC \rangle \\
\langle q_1, C \rangle & \xrightarrow{a} \langle q_2, C \rangle \\
\langle q_2, C \rangle & \xrightarrow{a} \langle q_2, \epsilon \rangle \\
\langle q_2, C \rangle & \xrightarrow{b} \langle q_1, CC \rangle 
\end{align*}
\]

The first state counts the initial \( a \)'s, the second state counts the \( b \)'s which follow, and the third state checks for the sum. In addition, the first state can nondeterministically decide that no \( b \)'s are going to come and that exactly half of the \( a \)'s have been read.

3. Consider the language:

\[ A = \{ x \in \{ a, b \}^* \mid \#a(x) < \#b(x) \} \]

(a) Give a context–free grammar \( G \) for \( A \). Explain your choice of productions.

**Solution:** There are many possible solutions. One way of looking at the strings of the language is to devide these into the ones which have exactly one occurrence of \( b \) more than occurrences of \( a \), and those that have more. A string is in the first group exactly when it can be represented as a string of the shape \( e_1 \cdot b \cdot e_2 \), where \( e_1 \) and \( e_2 \) are strings with an equal number of \( a \)'s and \( b \)'s. Thus, \( e_1 \) and \( e_2 \) can be produced by the grammar \( E \rightarrow \epsilon \mid aEb \mid bEa \mid EE \). A string is in the second group exactly when it is the concatenation of two strings of \( A \). So we arrive at the following grammar:

\[
\begin{align*}
S & \rightarrow EbE \mid SS \\
E & \rightarrow \epsilon \mid aEb \mid bEa \mid EE
\end{align*}
\]

(b) Construct an NPDA accepting \( A \) on empty stack. Explain its workings.
Solution: Again, there is a number of good solutions. One elegant solution using $\varepsilon$-transitions (proposed by one of the students at the exam) is based on the observation that if we use the "standard" productions for comparing occurrences:

$\langle q, \bot \rangle \xrightarrow{a} \langle q, A \bot \rangle$  
$\langle q, B \bot \rangle \xrightarrow{b} \langle q, BB \rangle$

$\langle q, A \rangle \xrightarrow{a} \langle q, AA \rangle$  
$\langle q, B \rangle \xrightarrow{b} \langle q, BB \rangle$

$\langle q, B \rangle \xrightarrow{a} \langle q, \varepsilon \rangle$  
$\langle q, A \rangle \xrightarrow{b} \langle q, \varepsilon \rangle$

then a string is in $A$ exactly when after reading it the stack contains only $B$’s (on top of $\bot$). Note that there must be at least one such $B$. So, we can obtain the desired behaviour by adding two more productions:

$\langle q, \bot \rangle \xrightarrow{b} \langle q, B \rangle$

$\langle q, B \rangle \xrightarrow{\varepsilon} \langle q, \varepsilon \rangle$

4. Consider the language:

$A = \{a^mb^n \mid m \leq n\}$

(a) Use the Pumping Lemma for regular languages (as a game with a Deamon) to prove that $A$ is not regular.

(b) Refer to the closure properties of context–free languages to argue that $A$ is context–free. That is, represent $A$ as the result of some operation(s) on context–free languages (which we already know to be context–free) under which CFLs are closed.

Solution: $A = B \cdot C$ for $B = \{a^mb^m \mid m \geq 0\}$ and $C = \{b^n \mid n \geq 0\}$, both of which we know to be context–free, and we know CFLs to be closed under language concatenation.

(c) Give a context–free grammar $G$ generating $A$.

Solution: One possibility is the grammar $S \rightarrow \varepsilon \mid aSb \mid Sb$.

(d) Prove your grammar correct. You are allowed to reuse results proved in class.

(e) Construct an NPDA accepting $A - \{\varepsilon\}$ on empty stack. Explain your choice of productions.

Solution: One solution is a NPDA with one control state $q$ and productions:

$\langle q, S \rangle \xrightarrow{a} \langle q, SA \rangle$

$\langle q, S \rangle \xrightarrow{a} \langle q, A \rangle$

$\langle q, A \rangle \xrightarrow{b} \langle q, A \rangle$

$\langle q, A \rangle \xrightarrow{b} \langle q, \varepsilon \rangle$

The automaton uses the first production for reading all initial $a$’s but the last, then guesses the last $a$ and uses the second production to get rid of the $S$ at the top of the stack. The stack now has as many $A$’s as the $a$’s read so far. The automaton guesses the number of $b$’s in excess of $a$’s in the string, and uses the third production that many times. The stack now has as many $A$’s as there are remaining (unread) $b$’s. The automaton uses production four to empty the stack upon reading the whole string.

5. Consider the language:

$A = \{a^kb^ma^n \mid l = k + m\}$

(a) Refer to the closure properties of regular languages to argue that $A$ is not regular.

Solution: The regular languages are closed under intersection, but $A \cap L(a^*b^*)$ equals $\{a^nb^m \mid n \geq 0\}$ which is not regular, hence $A$ cannot be regular.

(b) Refer to the closure properties of context–free languages to argue that $A$ is context–free.

Solution: The context–free languages are closed under language concatenation, and since $A$ can be represented as the concatenation of the context–free languages $\{a^kb^k \mid k \geq 0\}$ and $\{b^ma^m \mid m \geq 0\}$, $A$ must be context–free.
(c) Give a context–free grammar $G$ generating $A$.

**Solution:** From the previous observation, and the construction on grammars we used to show this closure property, we directly obtain the grammar:

\[
S \rightarrow AB \\
A \rightarrow \epsilon | aAb \\
B \rightarrow \epsilon | bBa
\]

(d) Construct an NPDA accepting $A - \{\epsilon\}$ on empty stack. Explain your choice of productions.

6. Consider the language:

\[
L \overset{\text{def}}{=} \{x \in \{a, b, c\}^* \mid \sharp a(x) + \sharp b(x) = \sharp c(x)\}
\]

(a) Show that $L$ is not regular.

(b) Give a context–free grammar for $L$. Prove your grammar correct.

(c) Construct an NPDA accepting $L$ (on empty stack).

7. Consider the language:

\[
L = \{a^m b^n \mid m \neq n\}
\]

(a) Give a simple argument for $L$ being context–free.

(Hint: you could use the closure properties of CFLs.)

(b) Construct an NPDA (possibly with $\epsilon$–transitions) accepting $L$ on empty stack. Explain its workings.

2.2 Chomsky–Schützenberger Theorem

8. Recall the Chomsky–Schützenberger Theorem, textbook Supplementary Lecture G. Show how this Theorem applies to the context–free language PAL of even–length palindromes over $\{a, b\}$, by identifying a suitable number $n$, a regular language $R$, and a homomorphism (renaming) $h$.

**Solution:** $\text{PAL}$ is equal to the language $h(PAREN_n \cap R)$ for $n = 2$, $R = L([1][1]^*([2][2])^*)$ and $h$ renaming $[1]$ and $[1]$ to $a$ and $[2]$ to $b$.

9. Recall the Chomsky–Schützenberger Theorem (textbook Supplementary Lecture G). Show how this theorem applies to the context–free language

\[
A \overset{\text{def}}{=} \{x \in \{a, b\}^* \mid \sharp a(x) = \sharp b(x)\}
\]

over the alphabet $\Sigma = \{a, b\}$, by identifying:

- a suitable natural number $n$,
- a regular language $R$ over the alphabet $\Sigma_n$ of the $n$–th balanced parentheses language, and
- a homomorphism $h : \Sigma_n \rightarrow \Sigma^*$,

for which you argue that $A = h(PAREN_n \cap R)$ holds.

**Solution:** Recalling that $A$ is generated by the grammar $S \rightarrow \epsilon | aSb | bSa | SS$ it is easy to see that $A = h(PAREN_n \cap R)$ holds for $n = 2$, $R = (\Sigma_n)^*$ and $h$ defined by $h([1]) = a$, $h([2]) = b$, $h([1]) = b$, $h([2]) = a$.

2.3 Proving Non–context–freeness of a Language

10. Apply the Pumping Lemma for context–free languages (as a game with the Demon) to show that the language:

\[
A = \{a^n b^n a^j \mid j \leq n\}
\]

is not context–free.

**Solution:**
11. A context–free grammar $G$ while the second shows that every regular language is the language of some SRLG.

In two parts: the first part shows that the languages generated by SRLGs are regular,

Solution: Use lemmas where needed to structure the proofs.

- Demon picks an arbitrary $k \geq 0$.
- We pick $z = a^kb^ka^k$ which is in $A$.
- Demon picks $u, v, w, x, y$ such that $z = uvwxy$, $|vx| > 0$, $|vwx| \leq k$.
- If $vwx = a^ib^m$ for some $l, m \geq 0$, we pick $i = 0$. Otherwise we pick $i = 2$.

Since $|vwx| \leq k$, $vwx$ has either the shape $a^ib^m$ or $b^ma^l$ for some $l, m$ such that $l + m \leq k$. In the first case $xv^0wx^0y$ must be of the shape $a^pb^qa^k$ for some $p, q$ such that $p + q < 2k$, and thus is not in $A$. In the second case, $xv^2wx^2y$ will either not be in $L(a^*ba^*)$ at all, and thus not in $A$, or else $xv^2wx^2y$ must be of the shape $a^*b^*a^*$ for some $p, q$ such that $p + q > 2k$, and thus not in $A$. Hence, we win the game in all cases, which shows that $A$ is not context–free.

2.4 Other Problems

11. A context–free grammar $G = (N, \Sigma, P, S)$ is called strongly right–linear (or SRLG for short) if all its productions are of shape $A \to aB$ or $A \to \epsilon$. Prove that SRLGs generate precisely the regular languages.

Hint: Define appropriate transformations between SRLGs and Finite Automata – one for each direction! – and prove that these transformations are language preserving. State and prove appropriate lemmas where needed to structure the proofs.

Solution: In two parts: the first part shows that the languages generated by SRLGs are regular, while the second shows that every regular language is the language of some SRLG.

a) Let $G = (N, \Sigma, P, S)$ be a SRLG. Define the NFA $N_G \text{ def } (N, \Sigma, \Delta, \{S\}, F)$ where we define $\Delta(X, a) \text{ def } \{Y \in N \mid (X \to aY) \in P\}$ and $F \text{ def } \{X \in N \mid (X \to \epsilon) \in P\}$. Then:

\[
x \in L(N_G) \iff \hat{\Delta}(\{S\}, x) \cap F \neq \emptyset \quad \text{Def. } L(N_G)
\]
\[
\iff \{X \in N \mid S \xrightarrow{a}^* xX \} \cap F \neq \emptyset \quad \text{Lemma A}
\]
\[
\iff \exists X \in N. (S \xrightarrow{a}^* xX \land X \to^*_G \epsilon) \quad \text{Def. } F
\]
\[
\iff S \xrightarrow{a}^* x \quad \text{Def. } \hat{\Delta}
\]
\[
x \in L(G) \quad \text{Def. } L(G)
\]

So $L(G) = L(N_G)$ and hence $L(G)$ is regular. In the proof, Lemma A states that

\[
\hat{\Delta}(\{Y\}, x) = \{X \in N \mid Y \xrightarrow{a}^*_G xX\}
\]

which is proved by induction on the structure of $x$ as follows.

Base case.

\[
\hat{\Delta}(\{Y\}, \epsilon) = \{Y\} = \{X \in N \mid Y \xrightarrow{a}^*_G xX\} \quad \text{Def. } \hat{\Delta}
\]

Induction. Assume the Lemma holds for $x$ (the ind. hyp.); we show that it then also holds for $xa$.

\[
\hat{\Delta}(\{Y\}, xa) = \bigcup_{X \in \hat{\Delta}(\{Y\}, x)} \Delta(X, a) = \bigcup_{X \in \{Z \in N \mid (X \to aZ) \in P\}} \Delta(X, a) = \{X \in N \mid Y \xrightarrow{a}^*_G xaX\}
\]

b) This part is similar to the previous one and is only sketched here. Let $A$ be a regular language.

Then there is a DFA $M_A = (Q, \Sigma, \delta, s, F)$ such that $L(M_A) = A$. We define the SLRG $G_A \text{ def } (Q, \Sigma, P, s)$ where $P = \{q_1 \to aq_2 \mid \delta(q_1, a) = q_2\} \cup \{q \to \epsilon \mid q \in F\}$. We then show $x \in L(G_A) \iff x \in L(M_A) = A$, the proof of which is best structured by proving and using Lemma B:

\[
q_1 \xrightarrow{a}^*_G xq_2 \iff \delta(q_1, x) = q_2
\]
12. A context–free grammar $G = (N, \Sigma, P, S)$ is called strongly right–linear (or SRLG for short) if all its productions are of shape $A \rightarrow aB$ or $A \rightarrow \epsilon$. Let us call a SRLG deterministic if for each non–terminal $A \in N$ and terminal $a \in \Sigma$ there is exactly one production of shape $A \rightarrow aB$ (while productions of shape $A \rightarrow \epsilon$ are optional).

Define a complement construction on deterministic SRLGs. That is, for deterministic SRLGs $G$ define the complement $\overline{G}$ as a deterministic SRLG for which you show that $L(G) = \overline{L(G)}$.

**Solution:** Recall that there is a one–to–one correspondence between DFAs and SRLGs, and recall the complement construction on DFAs. Let $G = (N, \Sigma, P, S)$ be a deterministic SRLG. We define the complement of $G$ as the deterministic SRLG $\overline{G} \stackrel{\text{def}}{=} (N, \Sigma, \overline{P}, S)$ where $\overline{P} \stackrel{\text{def}}{=} \{ A \rightarrow aB \mid A \rightarrow aB \in P \} \cup \{ A \rightarrow \epsilon \mid A \rightarrow \epsilon \not\in P \}$ is the set of productions of $G$. Then,

$$x \in L(\overline{G}) \iff S \xrightarrow{\overline{G}}^+ x \quad \{\text{Def. } L(G)\}$$

$$\iff \exists! A \in N. (S \xrightarrow{\overline{G}}^+ xA \land A \rightarrow \epsilon \in \overline{P}) \quad \{\overline{G} \text{ a deterministic SRLG}\}$$

$$\iff \exists! A \in N. (S \xrightarrow{\overline{G}}^+ xA \land A \rightarrow \epsilon \not\in \overline{P}) \quad \{\text{Def. } \overline{G}\}$$

$$\iff \text{not } S \xrightarrow{\overline{G}}^+ x \quad \{G \text{ a deterministic SRLG}\}$$

$$\iff x \not\in L(G) \quad \{\text{Def. } L(G)\}$$

$$\iff x \in \overline{L(G)} \quad \{\text{Set theory}\}$$

and therefore $L(\overline{G}) = \overline{L(G)}$. 
3 Turing Machines and Effective Computability

3.1 Constructing Turing Machines

1. Give a detailed description of a total Turing machine accepting the palindromes over \{a, b\}: that is, all strings \(x \in \{a, b\}^*\) such that \(x = \text{rev } x\).

Solution: We build a machine which repeatedly scans the tape from left to right, trying to match the first input symbol (which is directly replaced by the blank symbol) with the last input symbol (also directly replaced by the blank symbol).

2. Give a detailed description of a Turing machine with input alphabet \{a, ♯\} that on input \(a^m♯a^n\) halts with \(a^{(m \mod n)}\) written on its tape. Explain the underlying algorithm.

Solution: Here is one possible algorithm, consisting of three phases. It implements modulo division by repeated subtraction.

**Preparatory phase:** scan right to first blank symbol and replace it with \(\sqcup\).

**Main phase:** repeat in rounds, in each round performing:
- repeatedly scan from right to left, matching the rightmost \(a\) on the right of ♯ with the rightmost \(a\) on the left of ♯. The matching is done by replacing the corresponding \(a\)'s with \(\dot{a}\)'s.
- A round terminates in one of two possible ways:
  - (a) if there are no more \(a\)'s on the right of ♯, then delete (that is, replace with the blank symbol) all \(\dot{a}\)'s on the left of ♯, and restore all \(\dot{a}\)'s on the right of ♯ to \(a\)'s. Start new round.
  - (b) if there is no matching \(a\) on the left of ♯, then go to the next phase.

**Finalizing phase:**
- replace all \(\dot{a}\)'s by \(a\)'s on the left of ♯, and
- delete all other symbols on the tape.

3. Give a detailed description (preferably as a graph) of a total Turing machine accepting the language:

\[ A = \left\{ a^n b^{\frac{n(n+1)}{2}} \mid n \geq 0 \right\} \]

Explain the underlying algorithm.

Solution (Idea) We use the well–known equation \(\sum_{i=1}^{n} i = \frac{n(n+1)}{2}\). We proceed in rounds, in each round marking an \(a\) and then marking as many \(b\)'s as there are marked \(a\)'s (which equals the number of the current round).

4. Give a detailed description (preferably as a graph) of a Turing machine with input alphabet \{a, b\}, that on any input \(x\) halts with string \(y \in L(a^*b^*)\) written on its tape, where \(♯a(x) = ♯a(y)\) and \(♯b(x) = ♯b(y)\). Explain how your Turing machine achieves its task.

Solution: (Idea) There are many possible solutions, but one simple idea is to use insertion sort: Iteratively “swap” the left–most \(b\) with the first following \(a\) (using renaming), until there are no more such \(a\)'s. (6 states suffice!)

5. Let \(M\) range over deterministic finite automata (DFA).

(a) Describe a uniform, injective encoding of DFAs into strings over the alphabet \{0, 1\}.

Solution: Such an encoding was discussed in class.

(b) Let \(\hat{M} \in \{0, 1\}^*\) denote the encoding of \(M\). As we know from Cantor’s theorem, the set

\[ A \overset{\text{def}}{=} \left\{ \hat{M} \in \{0, 1\}^* \mid \hat{M} \not\in L(M) \right\} \]

is not regular (since it is the inverted diagonal set). Argue, however, that \(A\) is recursive by giving a (reasonably detailed) description of a total Turing machine accepting \(A\).

Solution: (Sketch) The Turing machine \(T\) starts by modifying the input \(\hat{M}\) to \(\hat{M}♯\hat{q}_0♯\hat{M}\) where \(q_0\) is the initial state of \(M\). The added part \(\hat{q}_0♯\hat{M}\) represents the initial configuration of \(M\) (where a configuration of a DFA is understood as a pair consisting of a state and the suffix of the input.
6. Consider the language:

\[ A = \{a^l b^m a^n \mid n = \max(l, m)\} \]

(a) Apply the Pumping Lemma for context-free languages (as a game with the Demon) to show that

\( A \) is not context-free.

(b) Give a detailed description (preferably as a graph) of a total Turing machine accepting \( A \).

7. Consider the language:

\[ L \overset{\text{def}}{=} \{ab, ababb, ababbabbb, ababbabbbabbbb, \ldots\} \]

(a) Show that \( L \) is not context-free.

(b) Describe a total Turing machine accepting \( L \). Explain the workings of your machine/algorithm.

(If possible, provide a graph of its control automaton.)

3.2 Proving Undecidability using Reduction

8. Argue that acceptance is not decidable: that is, that there is no total Turing machine \( M_A \) accepting the language \( L_A \overset{\text{def}}{=} \{\hat{M}\hat{x} \mid M \text{ accepts } x\} \), by reducing from the Halting problem.

**Solution:** A TM halts on input \( x \) if it either accepts \( x \) or otherwise rejects \( x \). We use this observation to show that the Halting problem (cf. Lecture 31) can be reduced to the above acceptance problem.

Assume that there is a total Turing machine \( M_A \) accepting \( L_A \). We can then build a machine \( M_R \) which, on any input \( \hat{M}\hat{x} \), first swaps the values of \( t \) and \( r \) in \( \hat{M} \) (that is, swaps the accepting and the rejecting states of \( M \)), and then behaves exactly like \( M_A \). Hence \( M_R \) is a total Turing machine deciding rejection. We can now combine \( M_A \) and \( M_R \) to produce a total Turing machine \( M_H \) deciding the Halting problem: for example, on any input \( \hat{M}\hat{x} \), let \( M_H \) first run as \( M_A \) and accept if \( M_A \) accepts, but continue as \( M_R \) if \( M_A \) rejects. \( M_H \) will thus accept \( \hat{M}\hat{x} \) if \( M \) halts on \( x \), and will reject \( \hat{M}\hat{x} \) otherwise.

But the Halting problem is undecidable, and therefore there is no total Turing machine \( M_A \) accepting \( L_A \). The acceptance problem is therefore undecidable.

9. Show that the problem of whether a Turing machine, when started on a blank tape, ever writes a given symbol (say \( a \)) of its input alphabet on its tape is not decidable.

Hint: You could reduce the undecidable problem of acceptance of the null string (problem (f), page 235) to the problem above.

**Solution:** Assume the problem was decidable. Then there must be a total Turing machine \( M_a \) deciding it. We shall use \( M_a \) to build a new total Turing machine \( M \), deciding the problem of acceptance of \( \epsilon \). (Since the latter is known to be undecidable, we shall conclude that the present problem is also undecidable.)

We construct \( M \), which, on input \( \hat{M} \), converts \( \hat{M} \) to \( \hat{M}' \) such that \( M' \) is like \( M \) but:

- \( a \) is renamed to a new letter which is added to the alphabet of \( \hat{M}' \),
- a new state \( q \) is added, which becomes the accepting state of \( \hat{M}' \), and
- transitions \( \delta(t, b) = (q, a, R) \) are added for every \( b \in \Gamma \).
Then rewind and run as \( M_a \) on \( M' \).

We can now deduce:

\[
M_\epsilon \text{ accepts } M \iff M_a \text{ accepts } M' \quad \{ \text{Def. } M_\epsilon \text{ and } M' \} \\
\iff M' \text{ reaches } t \text{ starting from } \epsilon \quad \{ \text{Def. } M_a \text{ and } M' \} \\
\iff M \text{ accepts } \epsilon \quad \{ \text{Def. } M' \}
\]

So, \( M_\epsilon \) decides the problem of acceptance of \( \epsilon \). Since the latter is known to be undecidable, we conclude that the present problem is also undecidable.

10. Consider the language

\[
VTP \overset{\text{def}}{=} \{ \hat{M}^\sharp x\sharp q \mid M \text{ run on } x \text{ visits } q \text{ twice} \}
\]

where "\( M \) visits \( q \)" means that Turing machine \( M \) is at a configuration with control state \( q \). Show that language \( VTP \) is not recursive by reducing from undecidability of the Membership Problem.

That is, given a total Turing machine \( M_{VTP} \) deciding \( VTP \), construct a total Turing machine \( M_{MP} \) deciding \( MP \), where:

\[
MP \overset{\text{def}}{=} \{ \hat{M}^\sharp x \mid M \text{ accepts } x \}
\]

**Solution:** Assume there is a total Turing machine \( M_{VTP} \) accepting \( VTP \). Then we can construct a Turing machine \( M_{MP} \) as follows.

On input \( \hat{M}^\sharp x \), \( M_{MP} \) modifies the input to \( \hat{M}'^\sharp x\sharp \hat{v} \) where \( M' \) is like \( M \) but is modified as follows: two new control states \( u \) and \( v \) are added, the latter of which is made the new accept state of \( M' \), and the transition function \( \delta \) of \( M \) is extended to \( \delta' \) so that \( \delta'(t, a) = (u, \hat{z}, R) \) and \( \delta'(u, a) = (t, a, L) \) for all \( a \) in the input alphabet of \( M \), and \( \delta'(t, \hat{z}) = (v, \hat{z}, R) \), where \( t \) is the original accept state of \( M \) and \( \hat{z} \) is a tape symbol of \( M_{MP} \) not used elsewhere. Notice that \( M' \) visits state \( t \) twice on input \( x \) exactly when \( M \) visits \( t \) on \( x \), that is, when \( M \) accepts \( x \). \( M_{MP} \) then continues as \( M_{VTP} \).

Then:

\[
M_{MP} \text{ accepts } \hat{M}^\sharp x \iff M_{VTP} \text{ accepts } \hat{M}'^\sharp x\sharp \hat{v} \\
\iff M' \text{ run on } x \text{ visits } \hat{v} \text{ twice} \\
\iff M \text{ accepts } x
\]

Since \( M_{VTP} \) is total, so is \( M_{MP} \), and so \( M_{MP} \) decides \( MP \) which we know to be undecidable. Hence there is no total Turing machine \( M_{VTP} \) accepting \( VTP \).

### 3.3 Rice’s Theorem

11. Recall Rice’s Theorem, textbook Lecture 34. Explain why the trivial properties of the recursively enumerable sets are decidable, by suggesting suitable total Turing machines for these properties.

**Solution:** There are exactly 2 trivial properties: the empty set (of r.e. sets) and the set of all r.e. sets. Since we represent every r.e. set by some (encoding of a) Turing machine accepting this set, the two trivial properties can be represented, by using some fixed encoding of Turing machines, as the languages \( \{ \hat{M} \mid \text{false} \} \), which is the empty set, and \( \{ \hat{M} \mid \text{true} \} \), which is the set of all legal Turing machine encodings.

A total Turing machine \( M_F \) accepting the first language is simply one that upon reading \( \rightarrow \) immediately enters its reject state, while a total Turing machine \( M_T \) accepting the second language is one which decides whether the input string is a legal encoding of some Turing machine according to the chosen encoding scheme.
