

DN2255: Exercise 1 – Reference solution plots

Here we show some plots for the temperature distribution, so that you may verify that your program works in task 2.4.

NOTE the scaling of the z-axis! It is a common mistake to multiply with one too many factors of Δx , Δy or Δt in the discretization of the PDE and get a surface that has the right shape, but the wrong range. For the steady state you should get $q(x, y, t \rightarrow \infty) = 0.5$.

Small suggestion Use the `caxis` command in Matlab to get consistent color mapping between plots, i.e. so that red corresponds to some fixed value instead of being scaled depending on data.
