- Examination
- Lecture material
- Registration

What is TL About?

Formalised properties of time-varying systems

- What time-varying systems?
- What properties?
- Algorithms
- Proof systems

This is why we think formalisation pays off

Some form of tractability

Our tasks:

- Show we can do useful stuff with this
- Understand and compare set-ups for expressiveness and tractability

What Time-Varying Systems?

- Continuous real-valued functions?
- Discrete program traces?
- Execution trees?
- Automata?
- Markov chains?
- Java code?
- Distributed processes?
- Real time? Or implicit time?
- Histories or future?
- Finite or infinite?
- Linear or branching? Tree shaped? Graph shaped?

Default Choice – Traces/Paths/Runs

Time is discrete

Starts at 0

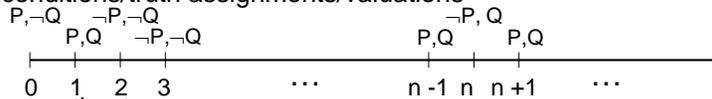

Goes on forever

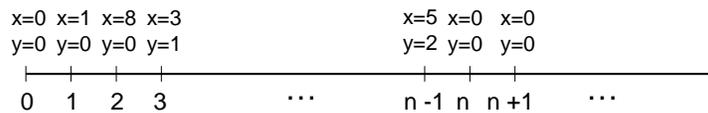

Time points decorated by events

Or conditions/truth assignments/valuations

Or execution traces

How Are Traces Produced?

- Maximal runs through a transition system/automaton
 - (Q, R, Q_0)
 - Q set of states
 - $R \subseteq Q \times Q$ transition relation, total
 - $Q_0 \subseteq Q$ initial states
 - Traces/runs $w = q_0 R q_1 R \dots R q_{n-1} R q_n R \dots$

In practice:

- Take your favourite programming/modeling language
- Equip it with discrete transition semantics
- Determine what should be observable events / conditions / execution states
- (Add looping at the end to get traces to be infinite)
- Off you go

Example - Concurrent While Language

Commands:

$\text{Cmd} ::= \text{skip} \mid x := e \mid \text{Cmd};\text{Cmd} \mid \text{if } e \text{ Cmd Cmd}$
 $\quad \mid \text{while } e \text{ Cmd} \mid \text{await } e \text{ Cmd} \mid \text{spawn Cmd}$
 $\quad \mid \text{Cmd} \parallel \text{Cmd}$

Stores $\sigma \in X \mapsto_{\text{fin}} V \in \text{Val}$

Configurations $c ::= \sigma \mid \langle \text{Cmd}, \sigma \rangle$

Example II

Transitions:

- $\sigma \rightarrow \sigma$ (... just to get looping ...)
- $\langle \text{skip}, \sigma \rangle \rightarrow \sigma$
- $\langle x := e, \sigma \rangle \rightarrow \sigma[x \mapsto \llbracket e \rrbracket \sigma]$
- $\langle \text{Cmd}_1; \text{Cmd}_2, \sigma \rangle \rightarrow \langle \text{Cmd}_1'; \text{Cmd}_2, \sigma' \rangle$
if $\langle \text{Cmd}_1, \sigma \rangle \rightarrow \langle \text{Cmd}_1', \sigma' \rangle$
- $\langle \text{Cmd}_1; \text{Cmd}_2, \sigma \rangle \rightarrow \langle \text{Cmd}_2, \sigma' \rangle$
if $\langle \text{Cmd}_1, \sigma \rangle \rightarrow \sigma'$
- (... remaining rules in class ...)

Conditions: Boolean/FO expressions in $\text{dom}(\sigma_i)$

Traces: $c_0 \rightarrow c_1 \rightarrow c_2 \rightarrow \dots \rightarrow c_{n-1} \rightarrow c_n \rightarrow \dots$

Linear Time Temporal Logic, LTL

Logic of temporal relations between events in a trace:

- Invariably (along this execution) $x \leq y + z$
- Sometime (along this execution) an acknowledgement packet is sent
- If thread T is infinitely often enabled (along this execution) then T is eventually executed

By no means the last word:

- Last packet received along channel a (along this execution) had the shape (b,c,d) (*past*)
- For all executions (from this state) there is an execution along which a reply is eventually sent (*branching*)
- No matter what choice B made in the past, it would necessarily come to pass that ψ (*historical necessity*)

LTL

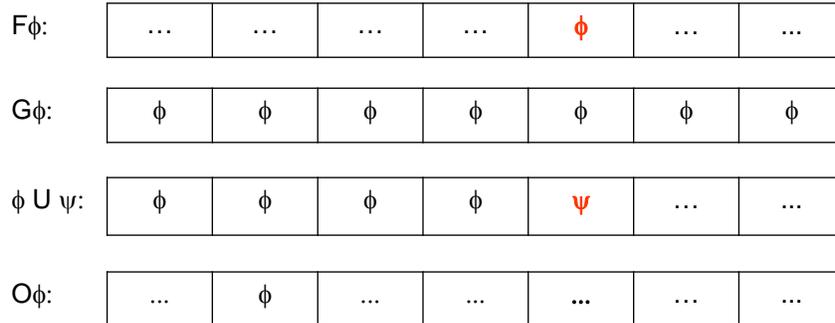

Syntax:

$\phi ::= P \mid \neg\phi \mid \phi \wedge \phi \mid F\phi \mid G\phi \mid \phi \text{ U } \psi \mid O\phi$

Intuitive semantics:

- P: Propositional constant P holds now/at the current time instant
- $F\phi$: At *some future* time instant ϕ is true
- $G\phi$: *For all future* time instants ϕ is true
- $\phi \text{ U } \psi$: ϕ is true *until* ψ becomes true
- $O\phi$: ϕ is true at the *next* time instant

Pictorially

Semantics

Run w

Satisfaction relation $w \models \phi$

Assume valuation v

$v(P)$: Set of states for which P holds

w^k : k 'th suffix of w

$w \models P$ iff $w(0) \in v(P)$

$w \models \neg\phi$ iff not $w \models \phi$

$w \models \phi \wedge \psi$ iff $w \models \phi$ and $w \models \psi$

$w \models F\phi$ iff exists $k \geq 0$. $w^k \models \phi$

$w \models G\phi$ iff for all $k \geq 0$. $w^k \models \phi$

$w \models \phi \cup \psi$ iff exists $k \geq 0$. $w^k \models \psi$ and for all i : $0 \leq i < k$. $w^i \models \phi$

$w \models O\phi$ iff $w^1 \models \phi$

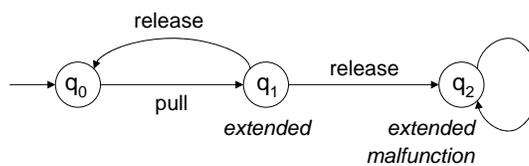

For transition system $T = (Q, R, Q_0)$ and all valuations v :

$T \models \phi$ iff for all runs w of T , $w \models \phi$

Some LTL Formulas

- $\phi \vee \psi = \neg(\neg\phi \wedge \neg\psi)$
- $\phi \rightarrow \psi = \neg\phi \vee \psi$
- $F\phi = \text{true} \text{ U } \phi$
- $G\phi = \neg F\neg\phi$
- $\phi \text{ V } \psi = []\psi \vee (\psi \text{ U } (\phi \wedge \psi))$
 - (sometimes called "release")
- $FG\phi$
 - ϕ holds from some point forever = ϕ holds *almost always*
- $GF\phi$
 - ϕ holds infinitely often (i.o.)
- $GF\phi \rightarrow GF\psi$
 - if ϕ holds infinitely often then so does ψ
 - Is this the same as $G(F\phi \rightarrow F\psi)$? As $GF(\phi \rightarrow \psi)$? As $FG\neg\phi \vee GF(\phi \wedge F\psi)$?

Spring Example

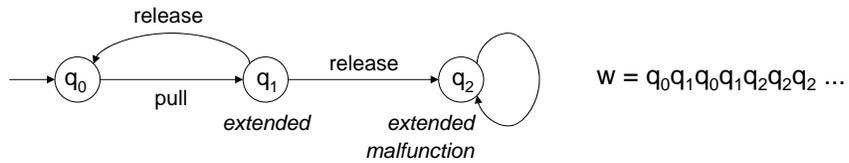

Conditions: *extended*, *malfunction*

Sample paths:

- $q_0 q_1 q_0 q_1 q_2 q_2 q_2 \dots$
- $q_0 q_1 q_2 q_2 q_2 \dots$
- $q_0 q_1 q_0 q_1 q_0 q_1 \dots$

Satisfaction by Single Path

For r :

$extended?$

$Oextended?$

$OOextended?$

$Fextended?$

$Gextended?$

$FGextended?$

$FGmalfunction?$

$GFextended?$

$extended \cup malfunction?$

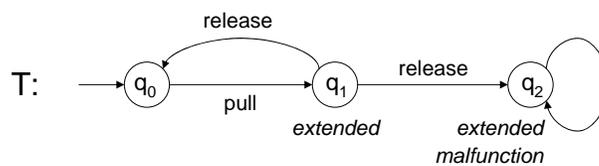

$(\neg extended) \cup extended?$

$(Fextended) \cup malfunction?$

$(F\neg extended) \cup malfunction?$

$G(\neg extended \rightarrow Oextended)$

Satisfaction by Transition System

For T:

$extended?$

$Oextended?$

$OOextended?$

$Fextended?$

$Gextended?$

$FGextended?$

$FGmalfunction?$

$GFextended?$

$extended \cup malfunction?$

$(\neg extended) \cup extended?$

$(Fextended) \cup malfunction?$

$(F\neg extended) \cup malfunction?$

$G(\neg extended \rightarrow Oextended)$

Example: Mutex

Assume there are 2 processes, P_l and P_r

State assertions:

- $tryCS_i$: Process i is trying to enter critical section
E.g. $tryCS_i: pc_i = l_4$
- $inCS_i$: Process i is inside its critical section
E.g. $inCS_i: pc_i = l_5 \vee pc_i = l_6$

Mutual exclusion:

$$G(\neg(inCS_l \wedge inCS_r))$$

Responsiveness:

$$G(tryCS_i \rightarrow F inCS_i)$$

Process keeps trying until access is granted:

$$G(tryCS_i \rightarrow ((tryCS_i \cup inCS_i) \vee GtryCS_i))$$

Example: Fairness

States: Pairs (q, α)

α label of last transition taken, so

$$\frac{q \xrightarrow{\alpha} q'}{(q, \beta) \xrightarrow{\alpha} (q', \alpha)}$$

Σ : Finite set of labels partitioned into subsets P

P : "(finite) set of labels of some process"

State assertions:

- en_P : Some transition labelled $\alpha \in P$ is enabled
i.e. $(q, \beta) \in v(en_{\alpha})$ iff $\exists q'. q \xrightarrow{\alpha} q'$
- $exec_P$: Label of last executed transition is in P
i.e. $(q, \alpha) \in v(exec_P)$ iff $\alpha \in P$

Note: $en_P \leftrightarrow \bigvee_{\alpha \in P} en_{\{\alpha\}}$ and $exec_P \leftrightarrow \bigvee_{\alpha \in P} exec_{\{\alpha\}}$

Fairness Conditions

Weak transition fairness:

$$\bigwedge_{\alpha \in \Sigma} \neg \text{FG}(\text{en}_{\{\alpha\}} \wedge \neg \text{exec}_{\{\alpha\}})$$

Or equivalently

$$\bigwedge_{\alpha \in \Sigma} (\text{FGen}_{\{\alpha\}} \rightarrow \text{GFexec}_{\{\alpha\}})$$

Strong transition fairness:

$$\bigwedge_{\alpha \in \Sigma} (\text{GFen}_{\{\alpha\}} \rightarrow \text{GFexec}_{\{\alpha\}})$$

Weak process fairness:

$$\bigwedge_P \neg \text{FG}(\text{en}_P \wedge \neg \text{exec}_P)$$

Strong process fairness:

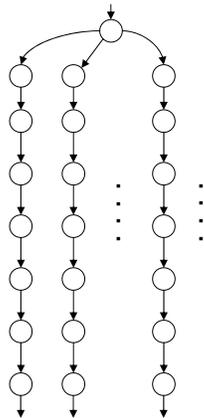

$$\bigwedge_P (\text{GFen}_P \rightarrow \text{GFexec}_P)$$

(Many other variants are possible)

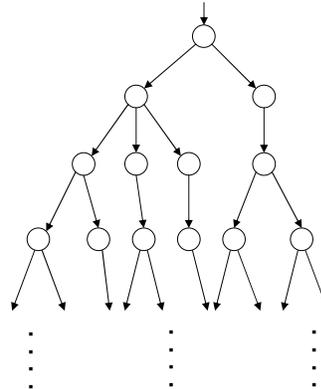

Exercise: Figure out which implications hold between these four fairness conditions. Draw a picture

Branching Time Logic

Sets of paths?

Or computation tree?

Computation Tree Logic - CTL

Syntax:

$\phi ::= P \mid \neg\phi \mid \phi \wedge \psi \mid AF\phi \mid AG\phi \mid A(\phi \cup \psi) \mid AX\phi$

Formulas hold of states, not paths

A: Path quantifier, along all paths from this state

So:

- $AF\phi$: Along all paths, at some future time instant ϕ is true
- $AG\phi$: Along all paths, for all future time instants ϕ is true
- $A(\phi \cup \psi)$: Along all paths, ϕ is true until ψ becomes true
- $AX\phi$: ϕ is true for all next states

Note: CTL is closed under negation so also express dual modalities EF, EG, EU, EX (E is existential path quantifier). Check!

CTL, Semantics

Valuation $v: P \mapsto Q' \subseteq Q$ as before

$q \models P$ iff $q \in v(P)$

$q \models \neg\phi$ iff not $q \models \phi$

$q \models \phi \wedge \psi$ iff $q \models \phi$ and $q \models \psi$

$q \models AF\phi$ iff for all w such that $w(0)=q$ exists $k \in \mathbb{N}$ such that $w(k) \models \phi$

$q \models AG\phi$ iff for all w such that $w(0)=q$, for all $k \in \mathbb{N}$, $w(k) \models \phi$

$q \models A(\phi \cup \psi)$ iff for all w such that $w(0)=q$, exists $k \in \mathbb{N}$ such that $w(k) \models \psi$ and for all $i: 0 \leq i < k$. $w(i) \models \phi$

$q \models AX\phi$ iff for all w such that $w(0) = q$, $w(1) \models \phi$

(iff for all q' such that $q \rightarrow q'$, $q' \models \phi$)

For transition system $T = (Q, R, Q_0)$:

$T \models \phi$ iff for all $q_0 \in Q_0$, $q_0 \models \phi$

CTL – LTL: Brief Comparison

LTL in branching time framework:

- $\phi \mapsto A\phi$ (ϕ to hold for all paths)

CTL $\not\subseteq$ LTL: $EF\phi$ not expressible in LTL

LTL $\not\subseteq$ CTL: FGP not expressible in CTL

CTL*: Extension of CTL with free alternation A, F, G, U, X

Advantages and disadvantages:

- LTL often "more natural"
- Satisfiability: LTL: PSPACE complete, CTL: DEXPTIME complete
- Model checking: LTL: PSPACE complete, CTL: In P

Adding Past

Add to LTL pasttime versions of the LTL future time modalities

Previously, some time in the past, always in the past, since

Theorem (Gabbay's separation theorem): Every formula in LTL + past is equivalent to a boolean combination of "pure pasttime" or "pure future time" formulas

Note: This applies regardless of whether time starts at 0 or at $-\infty$

Theorem (Elimination of past): Pasttime modalities do not add expressive power to LTL

But:

Theorem (Succinctness, LMS'02): LTL + past is exponentially more succinct than LTL

Expressive Completeness

LTL is easily embedded into FOL + linear order

FOL + linear order: First-order logic with 0 and $<$, unary predicate symbols, and interpreted over ω

Theorem (Kamp'68, GPSS'80, Expressive completeness)
If L is definable in FOL + linear order then L is definable in LTL

So Are We Done?

What about "every even state"

Theorem: A "every even state" P is not expressible in LTL, CTL, CTL*

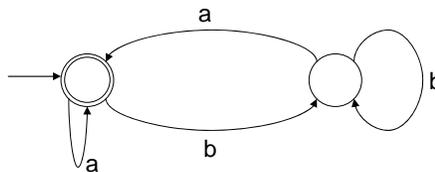

One solution:

- LTL formulas determine infinite words
- So: skip temporal logic (... temporarily ...) and use automata on infinite words instead

Automata Over Finite Words

Finite state automaton $A = (Q, \Sigma, \Delta, I, F)$:

- Q : Finite set of states
- Σ : Finite alphabet
- $\Delta \subseteq Q \times \Sigma \times Q$: Transition relation
Write $q \xrightarrow{a} q'$ for $\Delta(q, a, q')$ as before
- $I \subseteq Q$: Start states
- $F \subseteq Q$: Accepting states

Word $a_1 a_2 \dots a_n$ is accepted, if there is sequence

$$q_0 \xrightarrow{a_1} q_1 \xrightarrow{a_2} \dots \xrightarrow{a_n} q_n$$

such that $q_0 \in I$ and $q_n \in F$

Automata Over Infinite Words

Letters $a \in \Sigma$ can represent events, conditions, states

Infinite word $w \in \Sigma^\omega$:

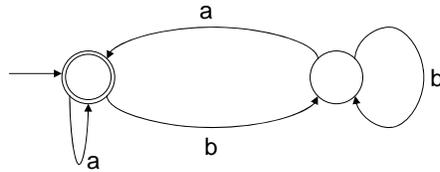

- Function $w: \omega \rightarrow \Sigma$
- Equivalently: Infinite sequence $w = a_0 a_1 a_2 \dots a_n \dots$
- Terminology: ω -words
- ω -words are traces / paths / runs

Buchi automaton: Finite state automaton, but on infinite words

ω -word w is *accepted* if accepting state visited infinitely often (!)

ω -language $L \subseteq \Sigma^\omega$ is *Buchi definable* if L is the set of ω -words accepted by some B. A.

Example

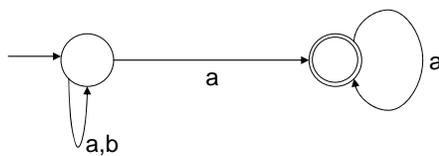

Which infinite words are accepted?

- ababab ... (= $(ab)^\omega$) ?
- aaaaaa... (= a^ω) ?
- bbbbbb... (= b^ω) ?
- aaabbbb... (= $aaab^\omega$) ?
- ababbabbbabbbba... ?

Nondeterminism

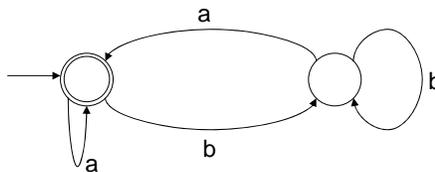

- What is the language accepted by this automaton?
- What is the corresponding LTL property if $b = \text{inCS}$ and $a = \neg b$?

Another Example

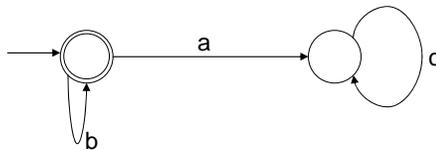

Letters represent propositions

Example: $G\text{FinCS}$, $a=\text{inCS}$, $b=\neg \text{inCS}$

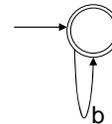

Yet More Examples

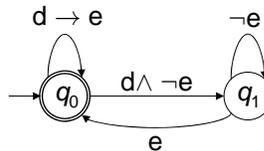

- $a = \text{inCS}_1 \wedge \text{inCS}_2$
- $b = \neg a$
- $c = \text{true}$
- Property: $G\neg a$

Or just:

- Property: $G(d \rightarrow Fe)$
- Idea:
 - q_0 : Have seen $\neg d \vee e$
 - q_1 : Saw d , now wait for e

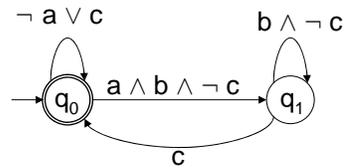

Even More...

Property: $G(a \rightarrow (bUc))$

Idea:

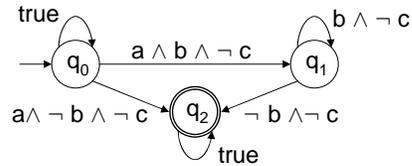

- q_0 : Body of G immediately ok
- q_1 : Awaiting c

Property: $\neg G(a \rightarrow (bUc)) = F(a \wedge \neg(bUc))$

Idea:

- $\neg(bUc)$: b becomes false some time without c having become true first
- q_0 : Waiting ...
- q_1 : Have seen a with b and $\neg c$
- q_2 : Committing ...

Generally

Theorem: If L is LTL definable then L is the set of words accepted by some B.A.

Why? The set of B.A. recognizable languages is closed under all LTL connectives

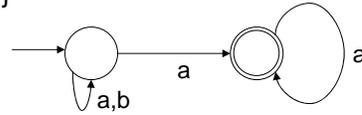

Hard case is complementation [Safra'88]

BTW then we can do LTL model checking:

- Represent model as B.A. A_1
- Represent LTL spec as A_2
- Emptiness of $L(A) = \{w \mid A \text{ accepts } w\}$ is polynomially decidable
- $L(A_1) \subseteq L(A_2)$ iff $L(A_1) \cap \neg L(A_2)$ is empty
- Example: The SPIN model checker

Aside: Deterministic Buchi Automata

Consider $\phi = FGa$ where $\Sigma = \{a,b\}$

Suppose A recognizes ϕ

A deterministic

A reaches accepting state on some input a^{n1}

And on $a^{n1}ba^{n2}$

And on $a^{n1}ba^{n2}ba^{n3}$

And on $a^{n1}ba^{n2}ba^{n3}b \dots b \dots b \dots$

So: Nondeterministic Buchi automata strictly more expressive than deterministic ones

And: Deterministic B. A. not closed under complement

Temporal Equations

Idea: Extend LTL with solutions of equations

- $\underline{F}\phi = \phi \vee \underline{O}\underline{F}\phi$
- $\underline{G}\phi = \phi \wedge \underline{O}\underline{G}\phi$
- $\underline{\phi U \psi} = \psi \vee (\phi \wedge \underline{O}(\underline{\phi U \psi}))$
- $\underline{\text{Even } \phi} = \phi \wedge \underline{OO}\underline{\text{Even } \phi}$

Complication: Solutions are not unique

Exercise: How many solutions (as sets L of traces/words w) can you find to the above four equations?

The Linear Time μ -calculus, L_μ

Formula $\phi(X)$ in free formula variable X determines function $\phi : L \mapsto \phi(L)$

If $\phi(X)$ is monotone in X then $\|\phi\|$ is monotone as function on $(\{L \mid L \subseteq \Sigma^\omega\}, \subseteq)$

Theorem (Tarski's fixed point theorem): A monotone function on a complete lattice has a complete lattice of fixed points

So, for each monotone $\phi(X)$ can find a largest and a smallest solution of equation $X = \phi(X)$

L_μ

Notation:

- $\mu X. \phi(X)$: Least solution of $X = \phi(X)$
- $\nu X. \phi(X)$: Greatest solution of $X = \phi(X)$

Note:

- $F\phi = \mu X. \phi \vee OX$
- $G\phi = \nu X. \phi \wedge OX$
- $\phi \cup \psi = \mu X. \psi \vee (\phi \wedge OX)$
- Even $\phi = \nu X. \phi \wedge OOX$

Exercise: Exchange μ and ν in the 4 examples above. What property is defined?

Hint: Which is the largest, resp. smallest L that solves the equation?

Expressiveness of L_μ

Theorem: An ω -language is definable in L_μ iff it is recognized by a B.A.

Direct proof:

\Leftarrow : Represent B.A. in L_μ (easy)

\Rightarrow : Show that B.A. definable languages are closed under all L_μ connectives. Hard part is μ , cf. (Dam, 92)

But many alternative characterizations exist

Alternative Characterizations

S1S: Monadic second order logic of successor

$$\exists X(0 \in X \wedge \forall y \forall z (\text{succ}(y,z) \rightarrow (y \in X \leftrightarrow \neg z \in X)) \\ \wedge \forall y (y \in X \rightarrow a(y)))$$

(all even symbols are a's)

QPLTL: LTL with propositional quantification

$$\exists X((X \wedge G(X \leftrightarrow O\neg X) \wedge G(x \rightarrow a))$$

ω -regular expressions

$$a((a \cup b)a)^\omega$$

Theorem (Buchi et al): An ω -language is recognized by a B.A. iff it is definable in one of L_μ , S1S, QPLTL, or as an ω -regular expression

What About Branching Time?

More difficult. Starting point are binary trees:

Theorem (Rabin): S2S (the monadic second-order theory of two successors) is decidable

For more general structures use e.g.

- Alternating tree automata
- Modal μ -calculus
- Parity games

Much activity in the past 10 years

But this is outside the scope of this course
